Land

Suitability Evaluation

ABSTRACT

This study was conducted on a 128-hectare land in Isua community of Edo state to assess its suitability for Oil palm, Coconut and Cocoa cultivation. Rigid grid Soil survey methodology at detailed scale was done which produced four mapping units. The soils were classified according to USDA soil taxonomy and local series; three soil orders were classified in the study area (Entisols-Ahiara, Inceptisols-Kulfo and Ultisols-Orlu). Major limitations to assessment were climate (mean annual temperatures) and soil physical characteristics (texture/structure). Aggregate suitability rating (both actual and potential) showed that Orlu series (pedons 3 and 4 amounting to 56.73 ha) was suitable for all the crops; Kulfo series (pedon 2, covering 54.25 ha) was suitable for Coconut and Cocoa; Ahiara series (Pedon 1 covering 17.13 ha) was not suitable for any of the crops. Thus, area occupied by pedon 1 should not be used for cultivation of any of the crops due to major limitation in texture. Moreover, both assessment approaches captured the major limitations; therefore, the use of any of the approaches employed in this study and for these crops becomes a matter of choice as both of them show no major differences in the application of their procedures.

1.0 Introduction

Considering the rapid growth of the world population, increasing demand and utilization of arable lands around the world, the dire need for effective and efficient utilization of the cropland has been felt more than ever. Land evaluation is the process of estimating the potentials of land for one use or several alternative uses (FAO 1976). It is the assessment of the capability of the land for producing a specific crop or combination of crops under specific management practices (FAO 1976; Egwu, 2015). Suitability assessment of land resources for cultivation for certain crops is the key for sustainable crop production, including landuse planning and policy making for agricultural crop production (Peter and Umweni, 2020)

Potentials of soils can readily be tapped when information

on its physical, chemical and biological properties are available. The need for proper land suitability evaluation before starting any Agricultural project cannot be over emphasized, as a neglect of this in the past has resulted to haphazard allocation of crops to portions of the landscape where they are not ecologically suited and this has led to the failure of massive agricultural projects.

Due to the tremendous advantages of cash crops such as Oil palm (*Elaeis guineensis*), Coconut (*Cocos nucifera*) and Cocoa (*Theobroma cacao*) in boosting the Nigerian industrial and economic development, attempts have been made to increase their production. To achieve this goal, it is necessary to have comprehensive information on the biophysical resource and identify the major limitations to the cultivation of specific crops in order to maximize landuse and increase production (Oko-Oboh *et al.*, 2018). Hence the

objective of this study was to assess the suitability of some soils of Isua community of Edo state for Oil palm (*Elais guineensis*) Coconut (*Cocos nucifera*) and Cocoa (*Theobroma cacao*) using Parametric and non-parametric approaches. Different scholars have used several guidelines for a study of this nature; however, the guidelines provided by Sys (1985) for Oil palm; Djaenudin *et al* (2003) as modified by Oko-Oboh *et al.*, (2018) for Coconut and Fasina *et al.*, (2007) for Cocoa were used in this study.

2.0. Materials and Methods

2.1. Study Area

The study was conducted on a 128 hectare land in Isua community (Uhunmwode Local Government) of Edo state. The site lies within latitude 6° 18'24.08"N and 6° 18'30.56"N and Longitude 5° 57'12.23"E and 5° 57'58.3"E . The annual rainfall is within the range of 1500 mm to 2500 mm with an average of 1900 mm per annum.

The average annual temperature ranges from 23-37°C, mean annual relative humidity ranging from 89% in the morning (10.00 am) to 75% in the evening (4 pm), (NIFOR,2013). Some of the crops grown include cassava, leafy vegetables, Oil palm.

The area is situated in the rainforest zone, with two distinct climatic seasons, namely; the rainy and dry seasons. The rainy season is between April and October with a 2-week break in August. The dry season lasts from November to April, with a cloudy, humid and dusty harmattan period between December and January.

The soils here are generally the red ferrasols, derived from coastal plain sands (unconsolidated sands and Sandy clay) and alluvial deposits (Umweni, 2007). Furthermore, the soils of the area were generally derived from the coastal plain sand which is Benin formations of sedimentary rock. The topography is a terrace (0.3-9%) throughout the study area.

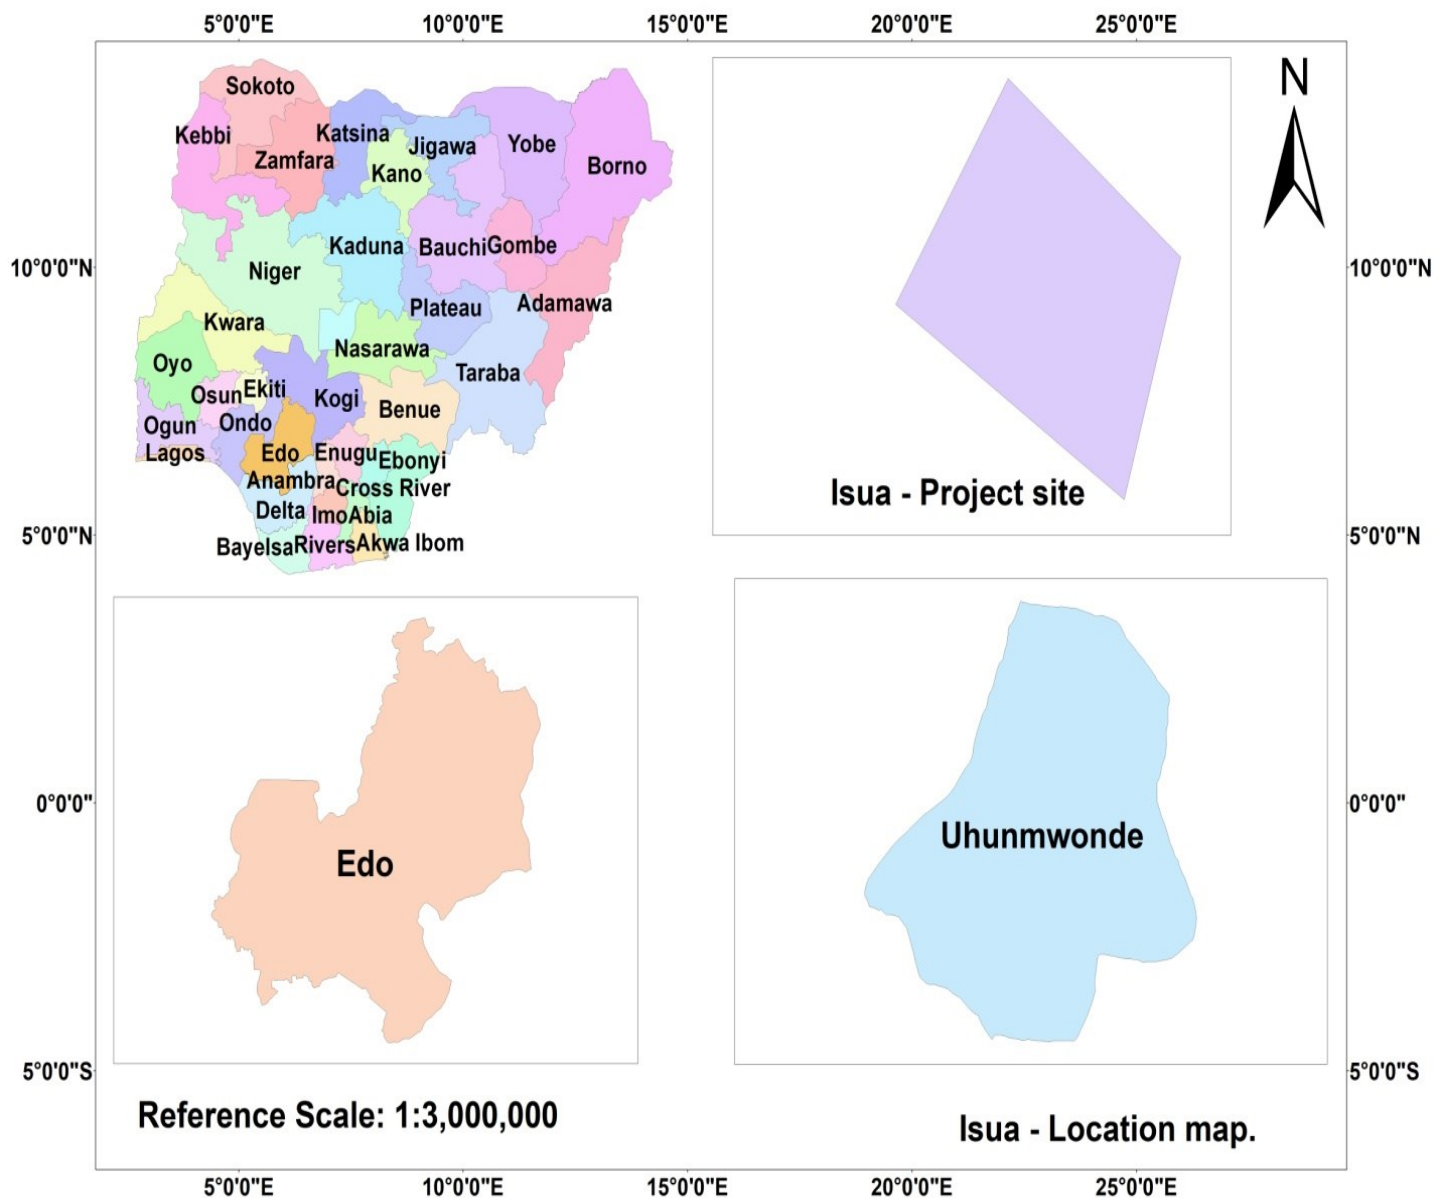

Fig: Map showing location of the study area

Fig: Map showing location of the study area

Field Studies

Soil survey process was by the rigid grid method at a detailed scale. Traverses were cut at intervals of 100 m from pre-determined baseline with the transverses running in both vertical and horizontal directions, making a total of 10 traverses. Auger borings were done at 100 meters apart along the traverses; auger samples were observed at depth intervals of 0-30 cm, 30-60 cm, 60-90 cm and 90-120 cm respectively and were appropriately described morphologically on the field (soil colour, texture by feel, presence or absence of mottles, presence or absence of concretions, and so on). Areas with similar properties were put together to form the various mapping units; four (4) mapping units were delineated. Each mapping unit was represented by a pedon that was described according to FAO (2006); identified horizons / layers were sampled from bottom to top. The samples were properly bagged, labelled and taken to the laboratory for analysis. The samples were analyzed using standard procedures.

Soil Classification

Soil classification was done using the USDA soil taxonomy (Soil Survey Staff, 2014) and locally according to Ogunkunle (1983).

Laboratory Analysis

Soil samples collected from each horizon were air-dried and passed through a 2mm sieve.

The sieved samples were analysed for some physical and chemical properties. Particle size distribution was determined by the hydrometer method (Gee and Or, 2002) after the removal of organic matter content with hydrogen per-

oxide and dispersion with sodium hexametaphosphate (International Institute for Tropical Agriculture - IITA, 1979). Available P was determined by Bray-1 method (Olsen and Sommers, 1982). The pH was determined with glass electrode pH meter in soil: soil and water at ratio 1:1 (Maclean, 1982). Exchangeable Bases (Na, K, Ca and Mg) were extracted with neutral normal ammonium acetate (NH₄OAC at pH 7.0); Na and K were determined by flame photometer while Ca and Mg were determined by atomic absorption spectro photometer (Thomas, 1982). Total N was determined by Macro Kjeldhal method (Bremner, 1996). Exchangeable Acidity was determined by titration method (Anderson and Ingram, 1993). Organic Carbon was determined by Walkley Black method (Page, 1982). Effective Cation Exchange Capacity (ECEC) was obtained by the summation of Exchangeable Bases and Exchangeable Acidity (Tan, 1996). Base Saturation was calculated by dividing the sum of Exchangeable Bases (Na, K, Ca and Mg) by the ECEC and multiplying the quotient by 100.

Land Suitability Evaluation

Land suitability evaluation was by both parametric and limitation methods. Limitation method was based on FAO (1976) frame work for rain fed agriculture and guidelines provided by Sys (1985) for Oil palm; Djaenudin *et al* (2003) as modified by Oko-Obloh *et al.*, (2018) for Coconut and Fasina *et al.*, (2007) for Cocoa. Pedons were placed in suitability classes by comparing their land qualities and characteristics with the guideline. The suitability class of a pedon (aggregate suitability) is that indicated by the most limiting (poorest) characteristics of that pedon. This was done in accordance with the principle of the law of minimum, which states that performance is always determined by the least favourable factor or plant nutrient in

the lowest supply (FAO, 1984).

For Parametric method, scores were given to the quality of each pedon and suitability was calculated as index of productivity using the square root model of Storie (1976)

$$IPc = A \sqrt{\frac{B}{100} * \frac{C}{100} * \frac{D}{100} * \frac{E}{100}} \text{----- (Equ. 1) (Sys 1985)}$$

(c) (t) (w) (s) (f)

Where A is the overall least characteristic rating, c = climate, t = topography, w = wetness, s = slope,

f = fertility.

Using this method, each characteristic was first rated as follows: No limitation: 100-85, (S1); Moderate limitation: 84-60 (S2); Severe limitation: 59-40 (S3); Very severe limitation 39-0 (N). The index of productivity for each pedon was expressed from the rating of each characteristics of the land qualities of each group, using the lowest rating. Index of productivity was rated into classes as follows:

Highly suitable (S1) 100-75, moderately suitable (S2) 74-50, marginally suitable (S3) 49-25 and Non suitable (N) 24-0. (Ogunkunle, 1993)

3.0. Results and Discussions

3.1. Soil Classification

Pedon 1 was classified as Typic Udipsamment (Ahiara); pedon 2 was classified as Typic Dystrudept (Kulfo); pedon 3 was classified as Typic Rhodudults (Orlu); pedon 4 was classified as Rhodic Kandudult [Orlu (Clayey)] by USDA soil taxonomy (Soil Survey Staff, 2014) and Locally by Ogunkunle (1983).

3.2. Limitation Approach

CLIMATE: According to the guidelines provided by Djaenudin *et al* (2003) as modified by Oko-oboh *et al.*, (2018) for Coconut; Sys (1985) for oil palm and Fasina *et al.*, (2007) for Cocoa, the mean annual rainfall of the study area is 1900mm (NIFOR, 2017). This according to the guideline falls in the class S₁ (highly suitable) for Coconut and Cocoa; and S₂ (Moderately suitable) for Oil Palm cultivation. The mean annual temperature of the study site ranges from 23°C to 37°C with a mean of 30°C, this placed the study area in class S₁ (highly suitable) for Oil palm and Cocoa; class S₃ (Marginally suitable) for Coconut. Length of Dry months was rated moderately suitable (S₂) Oil palm and Coconut and marginally suitable for Cocoa. Relative humidity (75-89%) was rated highly suitable for Coconut cultivation and marginally suitable for Cocoa according to the guidelines.

TOPOGRAPHY: Topography of the study area was highly suitable (S₁) for coconut and Cocoa in mapping units 1 (0.3-1.9%), 2 (3-5.2%) and 4 (3.5-5%) but moderately suitable (S₂) in mapping unit 3 (7.1-9%) (Sys 1985). However, mapping unit 1 was highly suitable for oil palm while mapping units 2, 3 and 4 were moderately suitable for (S₂) for oil palm. Djaenudin *et al.* (2003) as modified by Oko-oboh *et al.*, (2018), Fasina *et al.* (2007).

WETNESS:

The results showed that the study area has no flooding problem, it was well drained and results obtained from table showed that it falls under S₁ (Highly suitable) for all the crops according to the guidelines.

3.3. Soil Physical Characteristics:

The soil depth was greater than 100 cm in all the Pedons; which according to the guidelines (tables 2 and 3) is highly suitable for cultivation of Oil palm, Coconut and Cocoa. However, pedons 2, 3 and 4 were moderately suitable for Cocoa cultivation. Texture of pedon 1 was not suitable for all the crops (S-LS). Pedon 2 (S-SL) was not suitable for Oil palm, moderately suitable for Coconut and marginally suitable for Cocoa. Pedons 3 and 4 (LS-SCL) were highly suitable (S₁) for Coconut but marginally suitable (S₃) for Oil palm and Cocoa. Soil structure for pedon 1 was permanently not suitable (N₂) for Oil palm (single grain crumbs); and marginally suitable in pedons 2, 3 and 4 (ranged from single grain crumbs to sub-angular blocky) (Sys, 1985). Guidelines for Coconut and Cocoa did not include soil structure in their evaluation Djaenudin *et al* (2003) AS modified by (Oko-oboh *et al.*, 2018), (Fasina *et al.*, 2007).

Fertility Characteristics: This refers to the chemical fertility of the soil with reference to the properties that are easily altered (actual) as well as the requirements for potential fertility as it affects the production of Oil palm, Coconut and Cocoa.

The guidelines provided by Djaenudin, *et al.* (2003) as modified by Oko-oboh *et al.*, (2018) for Coconut and Sys (1985) for Oil palm, Fasina, *et al.* (2007) for Cocoa showed that Base saturation, which ranged from 28.32-73.68%, in all the pedons, placed Oil palm and Coconut in suitability class S₁ (highly suitable); however, pedons 1 and 2 were highly suitable while pedons 3 and 4 were moderately suitable for Cocoa cultivation. pH (4.6-6.4) ranged from strongly acid to slightly acid; a situation that is expected of acid sands (soils developed from coastal plain sand), rating pedon 1 highly suitable (S₁) while pedons 2, 3 and 4 were moderately suitable for Oil palm and Coconut according to the guidelines. In Pedon 1, Organic carbon/organic matter (0-30cm) ranging from 1.18- 3.46 % / 20.30-59.50gkg⁻¹, rated all the pedons S₁ (highly suitable) for all the crops. ECEC range of 1.27 – 4.34 cmolkg⁻¹ for all the pedons rated the study area S₂ (moderately suitable) for all the crops according to the guidelines Sys (1985), Djaenudin *et al* (2003) as modified by Oko-oboh *et al.*, (2018), Fasina *et al.*, (2007).

Suitability Class: Individual and Aggregate rating (both current and potential) of land characteristics was done for the four pedons encountered in the study area.

On actual suitability ratings, pedons 3 and 4 (56.73 ha) representing 44.28% of the study area was marginally suitable [S₃(s)] for Oil palm because of limitation in soil physical characteristics (texture); marginally suitable for Coconut and Cocoa [S₃(c)] because of limitation in climate (mean annual temperature / length of dry season). Pedon 2 (54.25 ha) representing 42.35% of study area was currently not suitable [N₁(s)] for Oil palm cultivation because of limitations in soil physical characteristics (texture/ structure), marginally suitable [S₃(c)] for coconut cultivation due to limitation in climate; marginally suitable [S₃(c,s)] for Cocoa due to limitation in climate and soil physical characteristics (texture). Pedon 1 (17.13 ha) representing 13.37% of the study area was permanently not suitable [N₂(s)] for all the crops due to limitation in soil physical characteristics (texture/structure).

However, on potential suitability rating, aggregate suitability classes did not change because the major limitations were soil physical characteristics (texture) and climate (temperature) which cannot be altered.

Parametric Approach

Actual (current) suitability rating showed that pedon 1 (17.13 ha) representing 13.37% of the study area was not suitable (N) for all the crops. Pedon 2 (54.25 ha) representing 42.35% of study area was not suitable (N) for Oil palm cultivation, marginally suitable (S₃) for coconut cultivation and moderately suitable (S₂) for Cocoa cultivation. Pedons 3 and 4 (56.73 ha) representing 44.28% of the study area were marginally suitable (S₃) for oil palm and moderately suitable for coconut and Cocoa cultivation.

Potential rating, showed that there was no difference in aggregate suitability classes which buttresses the fact that major limitations encountered in the study area cannot be altered.

The disparity in aggregate suitability ratings by both approaches (Parametric and limitation) indicates differences in the approaches; while just a characteristic that is not suitable

places a pedon in the not suitable class (N) under limitation approach, parametric approach takes all the characteristics into consideration. Thus, the parametric approach is truly an aggregate of the whole, in arriving at the final suitability class.

4.0 Conclusion

Parametric approach revealed that pedons 3 and 4 (Orlu) covering 56.73 ha, representing 44.28% of the study area were moderately suitable (S₂) for coconut cultivation (both potentially and currently); but marginally suitable for Oil palm cultivation. Pedon 2 (Kulfo) 54.25 ha, representing 42.35% of study area was marginally suitable for Coconut cultivation but not suitable for Oil palm cultivation; pedons 2,3 and 4 (Orlu and Kulfo) amounting to 110.98 ha, representing 86.63% were moderately suitable (S₂) for Cocoa cultivation; while pedon 1 (Ahiara) which covers 17.13 ha and represents 13.37% of the study area was not suitable for any of the crops. By limitation approach (both potential and current), pedons 2, 3 and 4 (Orlu and Kulfo), amounting to 110.98 ha and representing 86.63% of the study area were

marginally suitable (S_3) for Coconut and Cocoa cultivation; pedons 3 and 4 (Orlu), covering 56.73ha and representing 44.28% of the study area were marginally suitable for Oil palm; pedon 2 was not suitable for Oil palm cultivation while pedon 1 (Ahiara) covering 17.13 ha and representing 13.37% of the study area was not suitable for all the crops. Major limitations encountered were climate and soil physical characteristics. Area represented by pedon 1 (Entisols - 17.13 ha) should not be used for cultivation of any of the crops. Moreover, both assessment approaches (parametric and limitation) captured the major limitations (climate and soil physical characteristics) therefore, the use of any of the approaches employed in this study and for these crops becomes a matter of choice as both of them showed no major differences in the application of their procedures.
